# Python Program for SQL Query Execution

This program uses Python's built-in SQLite library to create a database, create a table, insert records, and execute a SELECT query.

## Program

```
import sqlite3

# Connect to database
con = sqlite3.connect("college.db")
cur = con.cursor()

# Create table
cur.execute("""
CREATE TABLE IF NOT EXISTS Students (
    id INTEGER PRIMARY KEY,
    name TEXT,
    mark INTEGER
)
""")

# Insert records
cur.execute("INSERT INTO Students (name, mark) VALUES ('Arun', 85)")
cur.execute("INSERT INTO Students (name, mark) VALUES ('Kumar', 90)")

con.commit()

# Execute SELECT query
cur.execute("SELECT * FROM Students")

# Display results
print("Student Records:")
print("----------------")

for row in cur.fetchall():
    print(row)

# Close connection
con.close()
```

## Expected Output

```
Student Records:\n----------------\n(1, 'Arun', 85)\n(2, 'Kumar', 90)
```

## Explanation

| Code | Purpose |
|---|---|
| import sqlite3 | Imports the SQLite database library. |
| sqlite3.connect() | Connects to the database; creates college.db if it does not exist. |
| con.cursor() | Creates a cursor used to execute SQL statements. |
| cur.execute() | Executes an SQL query. |
| con.commit() | Saves database changes. |
| cur.fetchall() | Retrieves all rows returned by the SELECT query. |
| con.close() | Closes the database connection. |

**Note:** Running the program again will insert the same two records again. For a fresh output, delete college.db before rerunning, or add a condition to avoid duplicate inserts.
